Partial eta squared is the ratio of variance associated with an effect, plus that effect and its associated error variance. The formula is similar to eta 2: Partial eta 2 = SS effect / SS effect + SS error. In fact, when you only have one independent variable, partial eta 2 is the same as eta 2

For ANOVAs, two of the most popular are Eta-squared and partial Eta-squared. In one way ANOVAs, they come out the same, but in more complicated models, their values, and their meanings differ. SPSS only reports partial Eta-squared, and in earlier versions of the software it was (unfortunately) labeled Eta-squared.

To check this claim, one can see that in Table 1, example 1 this formula yields 2500/ (5800 - 2500) = .76, which equals partial eta squared. To check this result, we hand calculated the partial correlation for factor A, using the correlation coefficients calculated from each main effect (in each case, r = .66).

**Eta Squared, Partial Eta Squared, and Misreporting of —**

Because partial eta squared values may, in some cases, be widely discrepant from the values of omega squared, epsilon squared, and eta squared, these reporting errors may lead to serious substantive errors in the interpretation of results. For these reasons, a closer look at eta squared and partial eta squared is warranted.

**Eta squared, partial eta squared, and misreporting of —**

Eta squared measures the proportion of the total variance in a dependent variable that is associated with the membership of different groups defined by an independent variable. Partial eta squared is a similar measure in which the effects of other independent variables and interactions are partialled out.

**Eta squared and partial eta squared as measures of effect —**

Eta-squared (??) and partial eta-squared (?p2) are effect sizes that express the amount of variance accounted for by one or more independent variables. These indices are generally used in conjunction with ANOVA, the most commonly used statistical test in second language (L2) research (Plonsky, 2013). Consequently, it is critical that these effect sizes are applied and interpreted appropriately.

Eta squared and partial Eta squared are estimates of the degree of association for the sample. Omega squared and the intraclass correlation are estimates of the degree of association in the population. SPSS for Windows 9.0 (and 8.0) displays the partial Eta squared when you check the display effect size option.
